

Segmentasi Citra

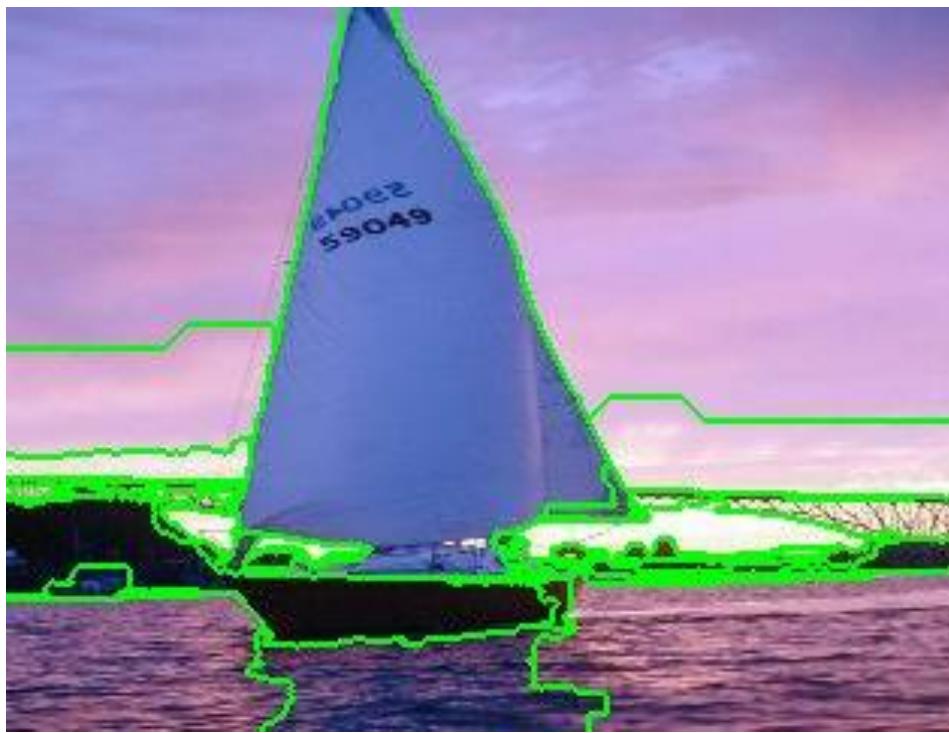

IF4073 Interpretasi dan Pengolahan Citra

Oleh: Rinaldi Munir

Program Studi Teknik Informatika
Sekolah Teknik Elektro dan Informatika
Institut Teknologi Bandung
2019

Tujuan

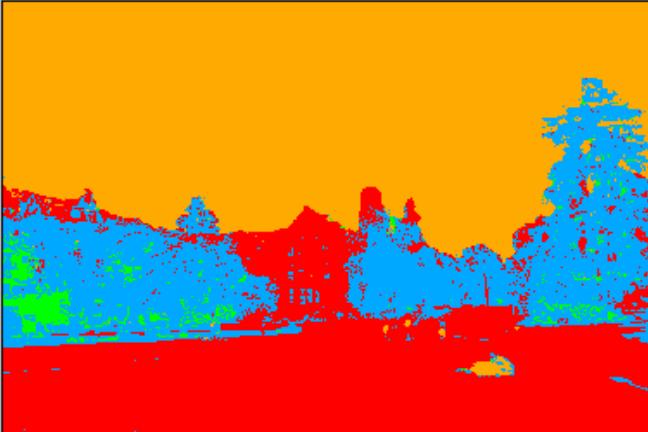

- Segmentasi citra (*image segmentation*) bertujuan untuk:
 1. membagi citra menjadi region-region atau objek-objek.
 2. memisahkan objek dengan latar belakang
- Citra disegmentasi berdasarkan properti yang dipilih seperti kecerahan, warna, tekstur, dan sebagainya.
- Segmentasi membagi citra menjadi sejumlah region yang terhubung, tiap region bersifat homogen berdasarkan properti yang dipilih.
- Segmentasi citra merupakan tahapan sebelum melakukan *image/object recognition, image understanding*, dll.

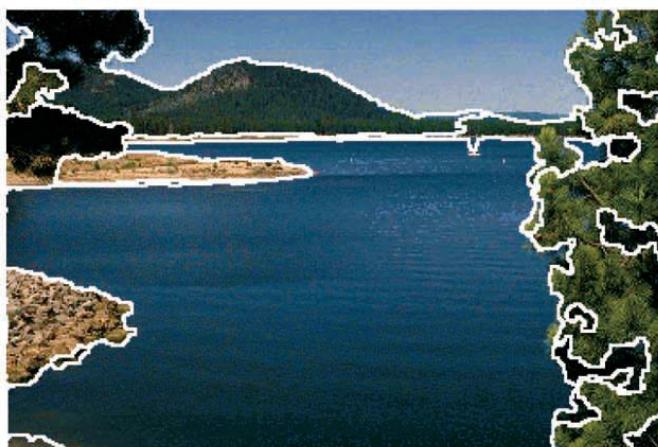

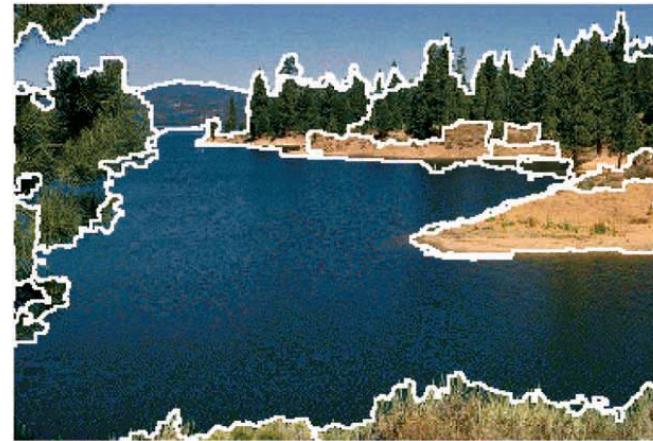

1. Select an image: 2. Select a processor: 3. Click

Options:

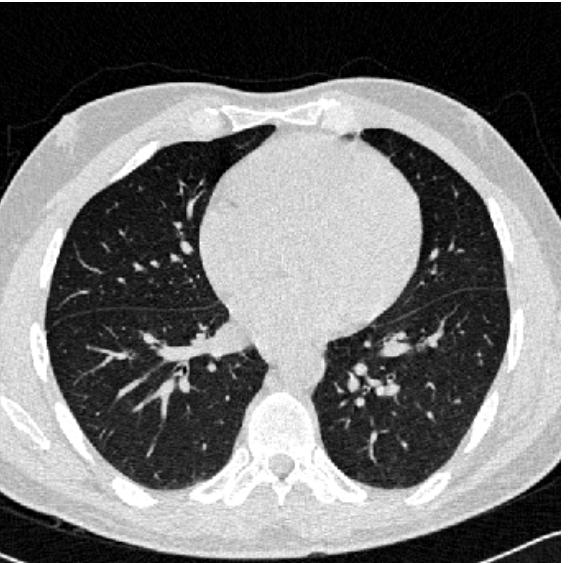

Init Method

640*480 (607,118): RGB(20,22,1) Process done! (228,26): RGB(255,170,0)

Citra medis

Hasil
segmentasi

Kriteria Segmentasi

- Menurut Pavlidis:

Segmentasi adalah partisi citra I menjadi sejumlah region $S_1, S_2, \dots S_m$ yang memenuhi persyaratan:

1. $\cup S_i = S$ Partisi mencakup keseluruhan pixel di dalam citra.
2. $S_i \cap S_j = \emptyset, i \neq j$ Tidak ada region yang beririsan.
3. $\forall S_i, P(S_i) = \text{true}$ P = Predikat homogenitas, dipenuhi oleh setiap region
4. $P(S_i \cup S_j) = \text{false}, i \neq j, S_i$ adjacent S_j Gabungan region bertetangga tidak memenuhi predikat

Jadi, yang harus dilakukan adalah mendefinisikan dan mengimplementasikan predikat *similarity*

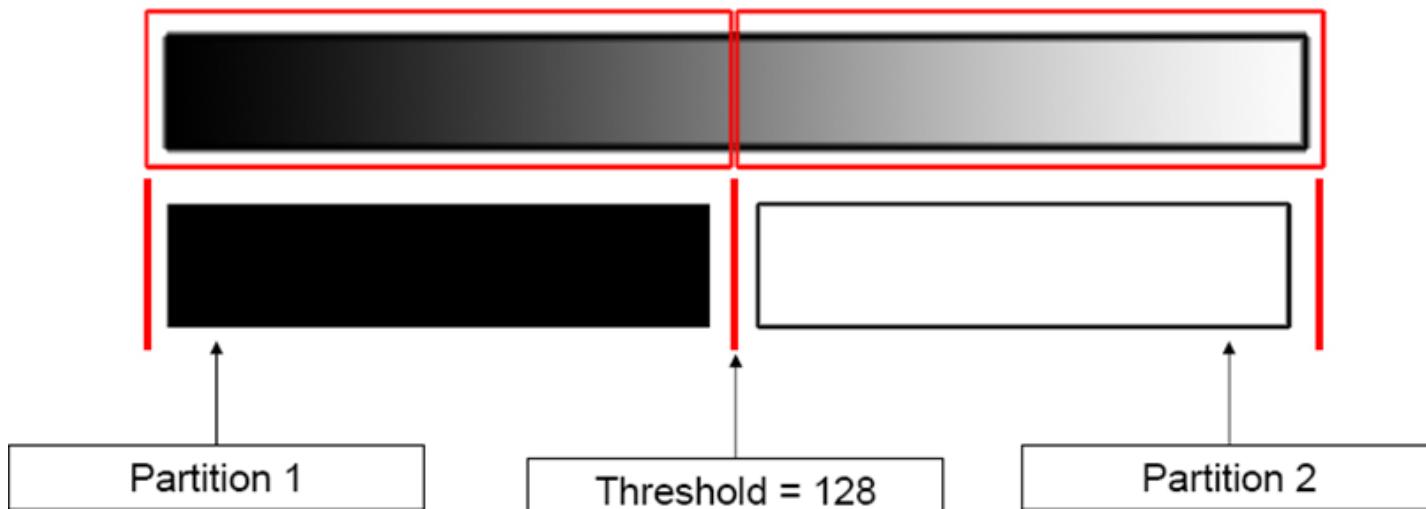

Metode segmentasi

Metode-metode yang digunakan untuk melakukan segmentasi region adalah:

1. Pengambangan (*thresholding*)
2. *Region growing*
3. *Split and merge*
4. *Clustering*

Pengambangan

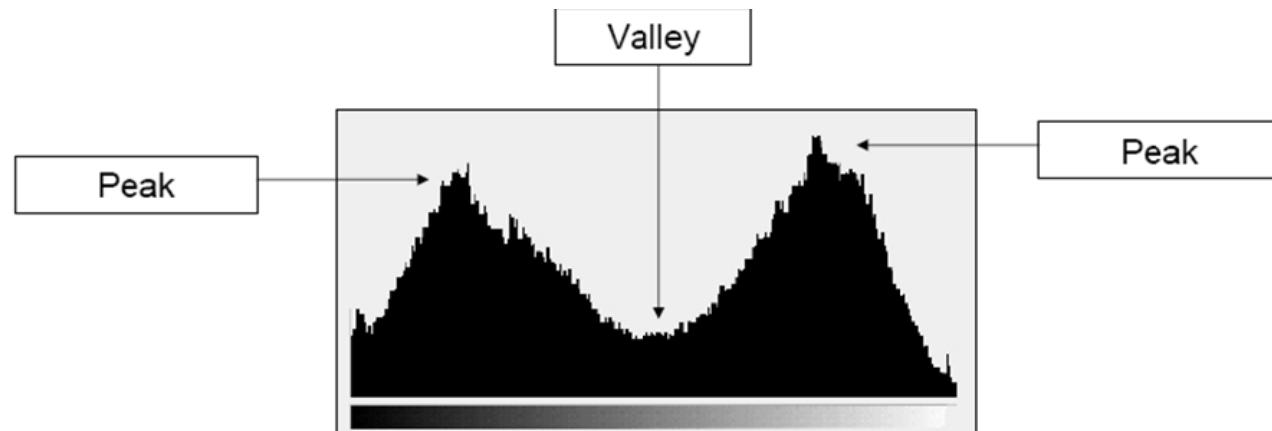

- Sudah dijelaskan pada materi sebelumnya (lihat materi Citra Biner)
- Segmentasi citra didasarkan pada nilai intensitas pixel-pixel dan niali ambang T .
- Salah satu cara untuk mengekstrak objek dari latar belakang adalah dengan memilih ambang T .
- Setiap pixel (x, y) pada citra di mana $f(x, y) > T$ disebut titik objek, jika tidak maka akan disebut latar belakang.
- Hasil segmentasi adalah berupa citra biner

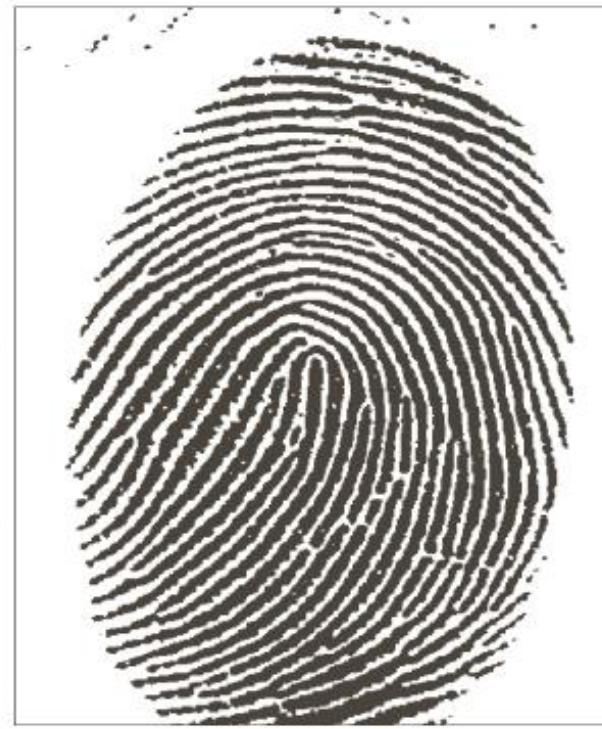

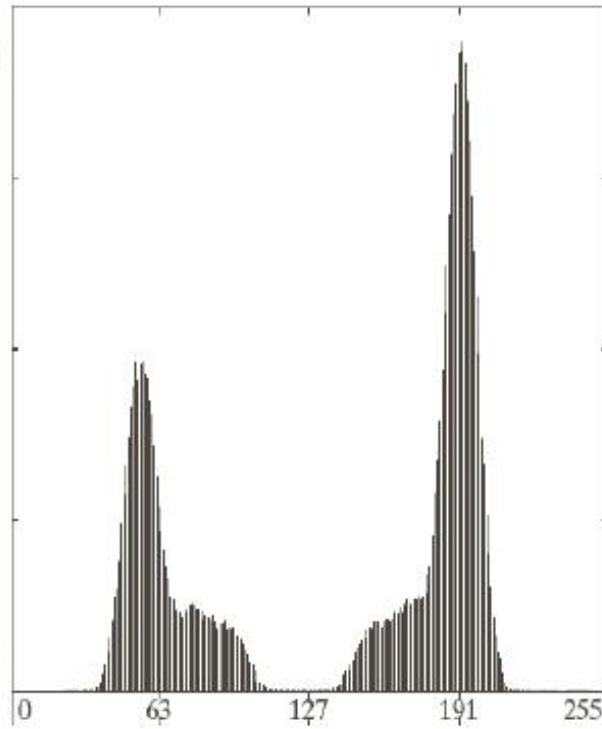

Pilih nilai ambang T

1. Pixel-pixel di atas nilai ambang mendapatkan intensitas baru A.
2. Pixels di bawah nilai ambang mendapatkan intensitas baru B.

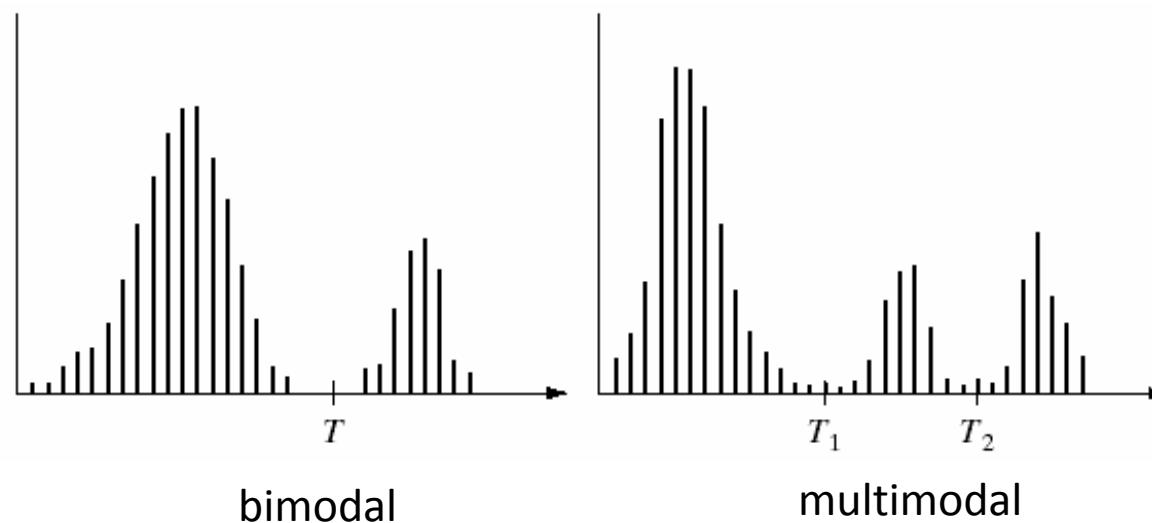

- Untuk mendapatkan nilai ambang T , analisis histogram citra lalu identifikasi puncak dan lembah.

- Nilai *grayscale* pada lembah terdalam di antara dua bukit menyatakan nilai T .

- Mencari nilai T dengan cara sederhana di atas hanya tepat jika histogram bersifat bimodal (mempunyai dua puncak dan satu lembah). Misalnya segmentasi teks dengan latar belakangnya.
- Jika terdapat multimodal di dalam citra, maka diperlukan beberapa nilai ambang.

- Teknik pengambangan dibagi menjadi:
 1. *Global thresholding*
Nilai ambang bergantung pada keseluruhan nilai-nilai pixel
 2. *Local thresholding*
Nilai ambang bergantung pada pixel-pixel bertetangga, hanya untuk sekelompok pixel saja.
 3. *Adaptive thresholding*
Nilai ambang berubah secara dinamis bergantung pada perubahan pencahayaan di dalam citra

Global thresholding

Sumber: Image segmentation
Stefano Ferrari
Universit`a degli Studi di Milano
stefano.ferrari@unimi.it

A simple algorithm:

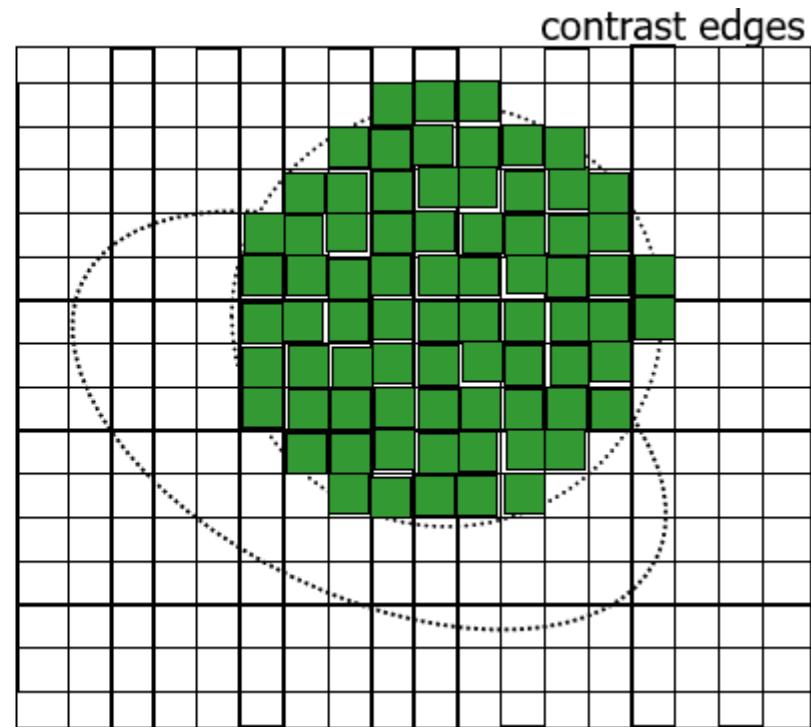

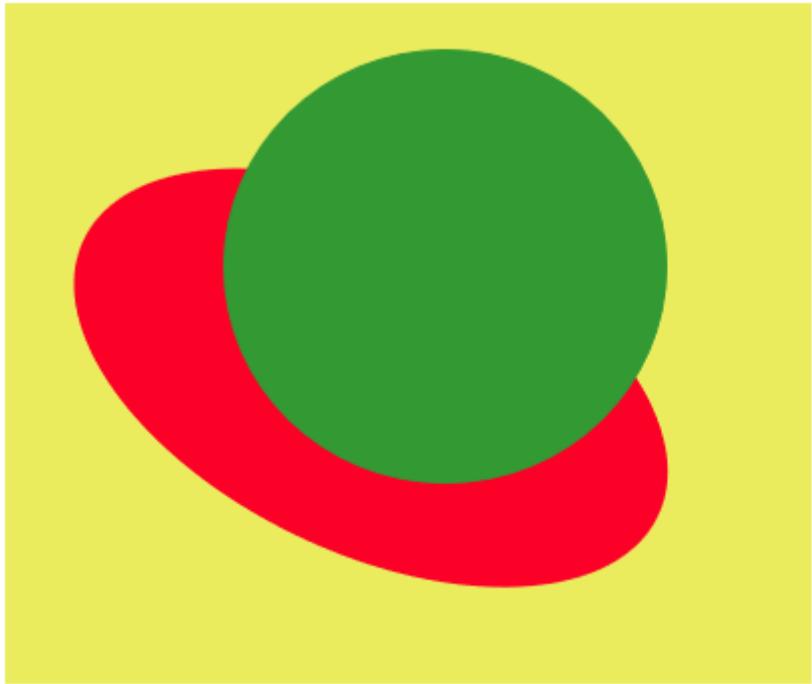

1. Initial estimate of T
2. Segmentation using T :
 - ▶ G_1 , pixels brighter than T ;
 - ▶ G_2 , pixels darker than (or equal to) T .
3. Computation of the average intensities m_1 and m_2 of G_1 and G_2 .
4. New threshold value:

$$T_{\text{new}} = \frac{m_1 + m_2}{2}$$

5. If $|T - T_{\text{new}}| > \Delta T$, back to step 2, otherwise stop.

Region Growing

- *Region growing*: kelompok *pixel* atau sub-region yang tumbuh menjadi region yang lebih besar.
- Algoritma: Mulai dengan “umpan (*seed*)” yang berisi himpunan beranggota satu atau lebih *pixel* dari region yang potensial, dan dari sini *region* berkembang dengan menambahkan pada umpan *pixel-pixel* tetangga yang memiliki properti yang mirip dengan umpan, lalu berhenti jika *pixel-pixel* tetangga tidak mirip lagi.
- Biasanya uji statistik digunakan untuk memutuskan apakah sebuah *pixel* dapat digabungkan ke dalam region atau tidak.
- Keuntungan: memiliki keterhubungan yang bagus antar pixel di dalam region
- Kelemahan:
 - pemilihan umpan yang tepat
 - kriteria berhenti
 - mengkonsumsi waktu yang lama

Split and Merge

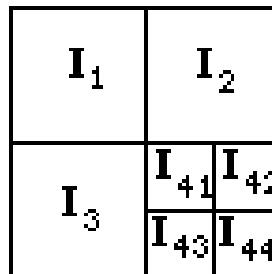

- Menggunakan algoritma *divide and conquer*
- Citra dibagi (split) menjadi sejumlah region yang *disjoint*
- Gabung (*merge*) region-region bertetangga yang homogen

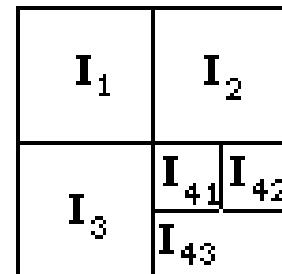

(a) Whole Image

(b) First Split

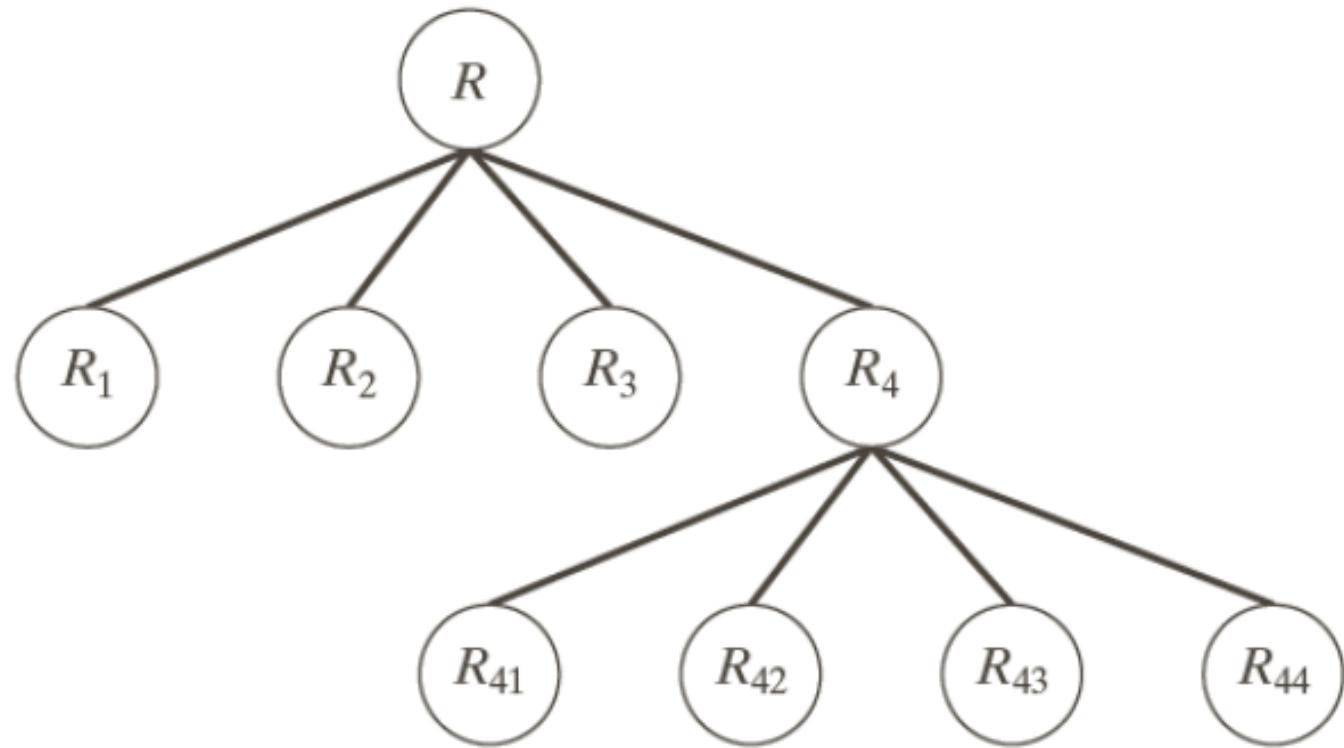

(c) Second Split

(d) Merge

	R_1	R_2
	R_{41}	R_{42}
R_3		
	R_{43}	R_{44}

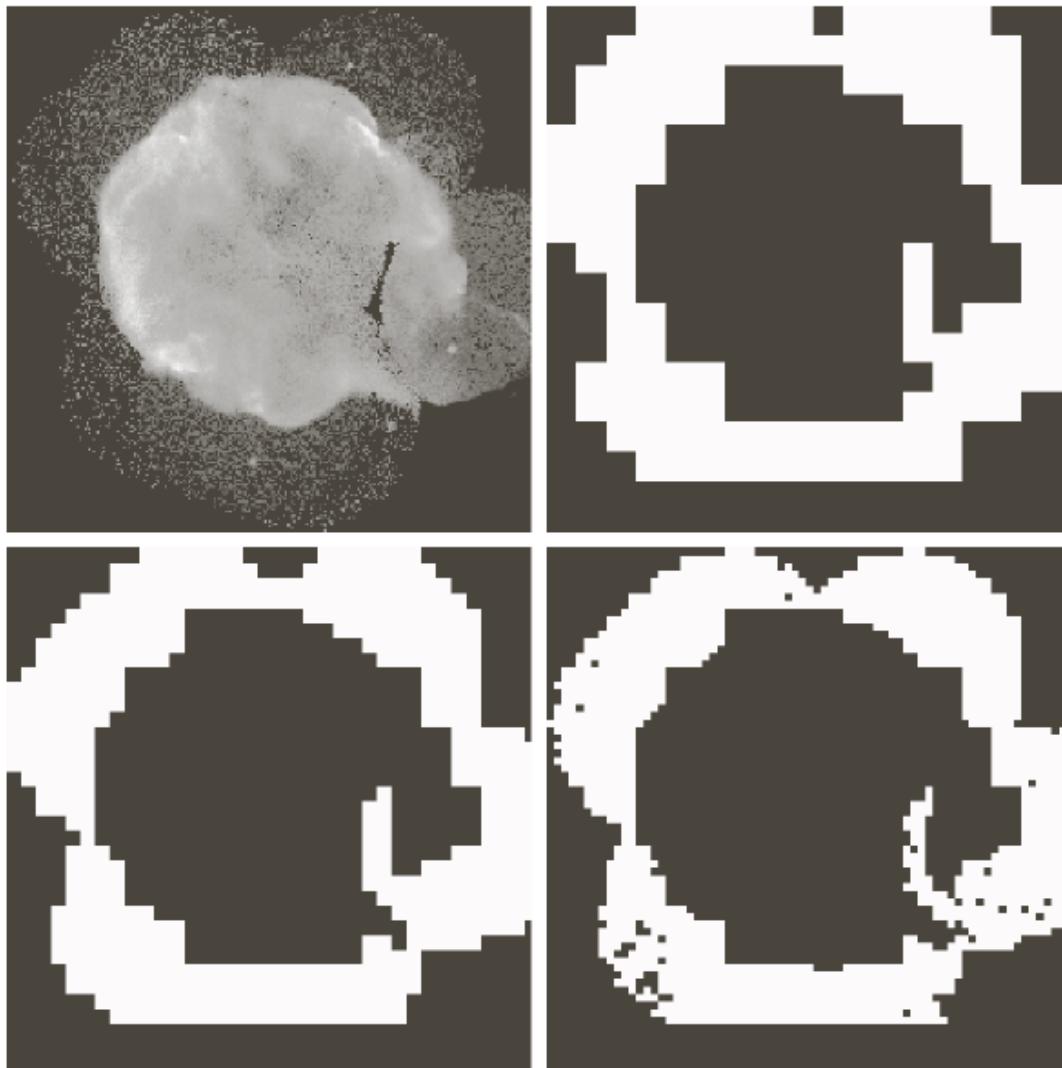

Algoritma *Split & Merge*

Given an image f and a predicate Q , the basic algorithm is:

1. $R_1 = f$
2. Subdivision in quadrants of each region R_i for which $Q(R_i) = \text{FALSE}$.
3. If $Q(R_i) = \text{TRUE}$ for every regions, merge those adjacent regions R_i and R_j such that $Q(R_i \cup R_j) = \text{TRUE}$; otherwise, repeat step 2.
4. Repeat the step 3 until no merging is possible.

Clustering

Prinsip *clustering* secara umum

- Misalkan terdapat N buah titik data (terokan, vektor fitur), x_1, x_2, \dots, x_N
- Kelompokkan (*cluster*) titik-titik yang mirip dalam kelompok yang sama

Bagaimana kaitan *clustering* pada segmentasi citra?

- Nyatakan citra sebagai vektor fitur x_1, \dots, x_n
 - Sebagai contoh, setiap *pixel* dapat dinyatakan sebagai vektor:
 - Intensitas, → menghasilkan vektor dimensi satu
 - Warna → menghasilkan vektor berdimensi tiga (R, G, B)
 - Warna + koordinat, → menghasilkan vektor berdimensi lima
- Kelompokkan vektor-vektor fitur ke dalam k kluster

RGBXY (or LUVXY) space clustering

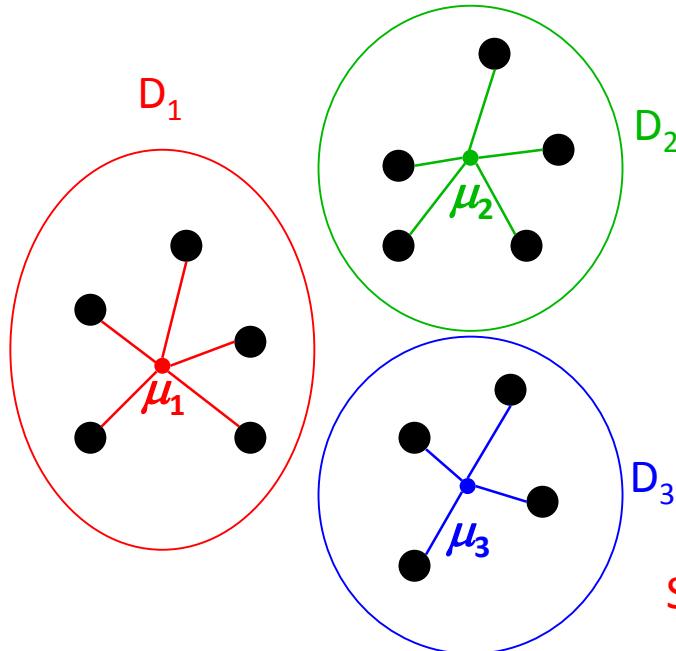

K-Means Clustering

- *K-means clustering* merupakan algoritma *clustering* yang paling populer
- Asumsikan jumlah cluster adalah k
- Mengoptimalkan (secara hampiran) fungsi objektif berikut untuk variabel D_i dan μ_i

$$E_k = SSE = \sum_{i=1}^k \sum_{x \in D_i} \|x - \mu_i\|^2$$

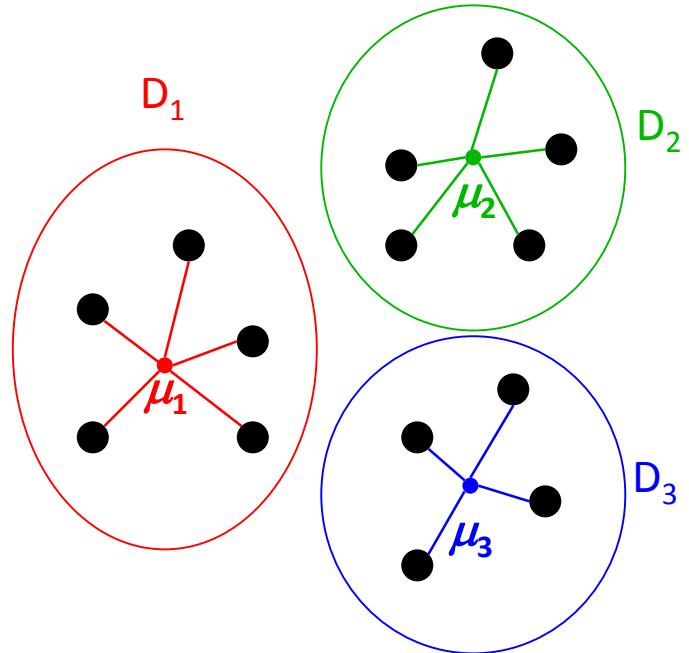

sum of squared errors

dari kluster dengan pusat μ_i

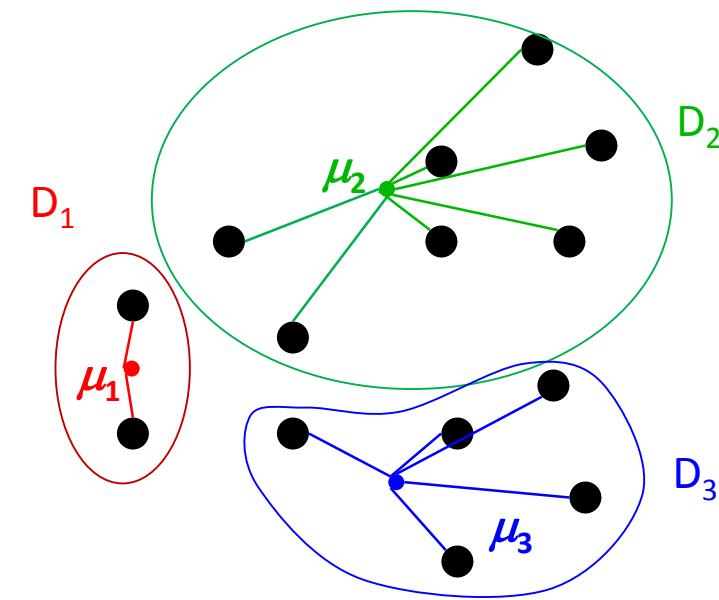

$$SSE = \text{[Red Cluster SSE]} + \text{[Green Cluster SSE]} + \text{[Blue Cluster SSE]}$$

Sumber: CS 4487/9587 Algorithms for Image Analysis: Basic Image Segmentation

$$SSE = \text{Red Star} + \text{Green Star} + \text{Blue Star}$$

Good (tight) clustering
smaller value of SSE

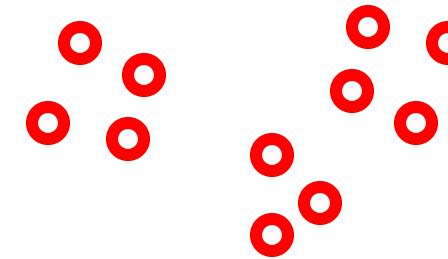

$$SEE = \text{Red Star} + \text{Green Star} + \text{Blue Star}$$

Bad (loose) clustering
larger value of SEE

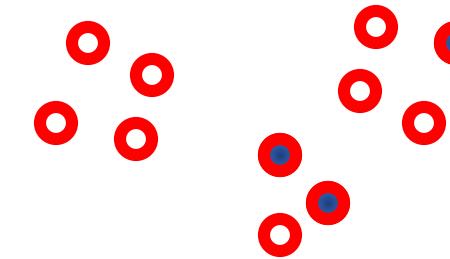

Algoritma K-means Clustering

- Initialization step
 1. pick k cluster centers randomly

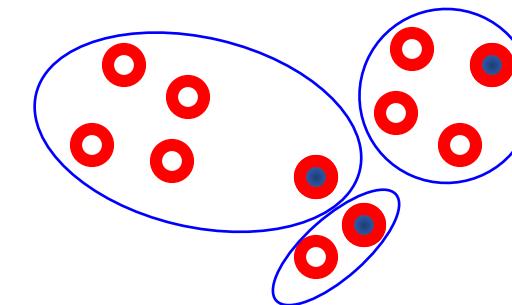

Algoritma K-means Clustering

Algoritma K-means Clustering

- Initialization step
 1. pick k cluster centers randomly
 2. assign each sample to closest center

- Iteration steps
 1. compute means in each cluster $\mu_i = \frac{1}{|D_i|} \sum_{x \in D_i} x$

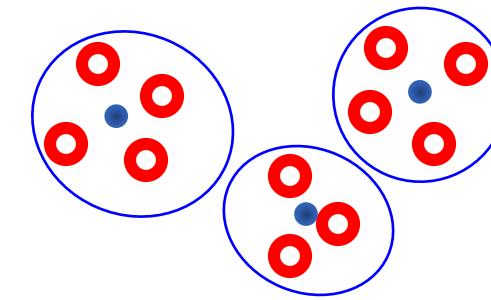

Algoritma K-means Clustering

- Initialization step
 1. pick k cluster centers randomly
 2. assign each sample to closest center
- Iteration steps
 1. compute means in each cluster $\mu_i = \frac{1}{|D_i|} \sum_{x \in D_i} x$
 2. re-assign each sample to the closest mean

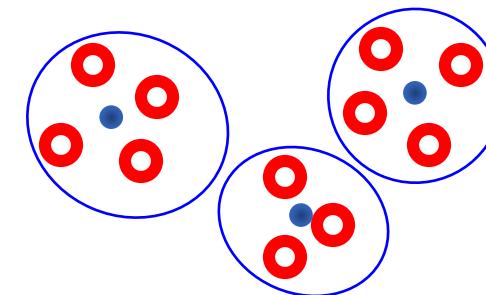

Algoritma K-means Clustering

- Initialization step
 1. pick k cluster centers randomly
 2. assign each sample to closest center
- Iteration steps
 1. compute means in each cluster $\mu_i = \frac{1}{|D_i|} \sum_{x \in D_i} x$
 2. re-assign each sample to the closest mean
- Iterate until clusters stop changing

Algoritma K-means Clustering

- Initialization step
 - pick k cluster centers randomly
 - assign each sample to closest center

- Iteration steps
 - compute means in each cluster $\mu_i = \frac{1}{|D_i|} \sum_{x \in D_i} x$
 - re-assign each sample to the closest mean
- Iterate until clusters stop changing

- This procedure decreases the value of the objective function

$$E_k(D, \mu) = \sum_{i=1}^k \sum_{x \in D_i} \|x - \mu_i\|^2$$

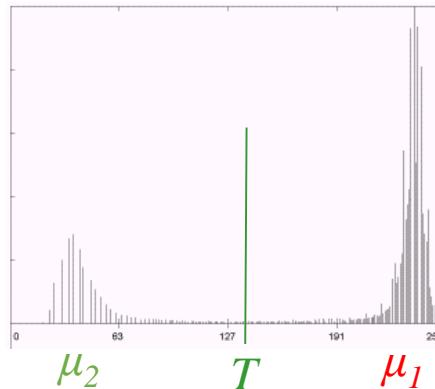

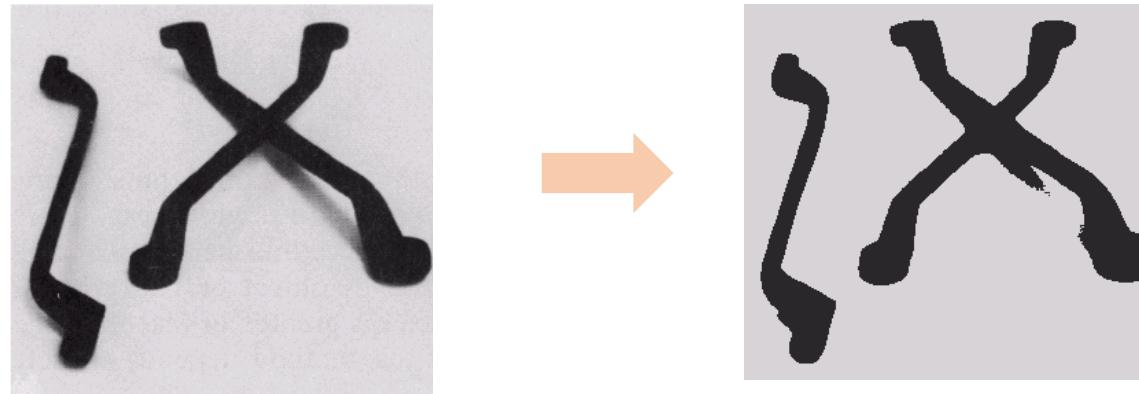

optimization variables

$$D = (D_1, \dots, D_k)$$

$$\mu = (\mu_1, \dots, \mu_k)$$

block-coordinate descent: step 1 optimizes μ , step 2 optimizes D

Contoh hasil *K-means clustering*

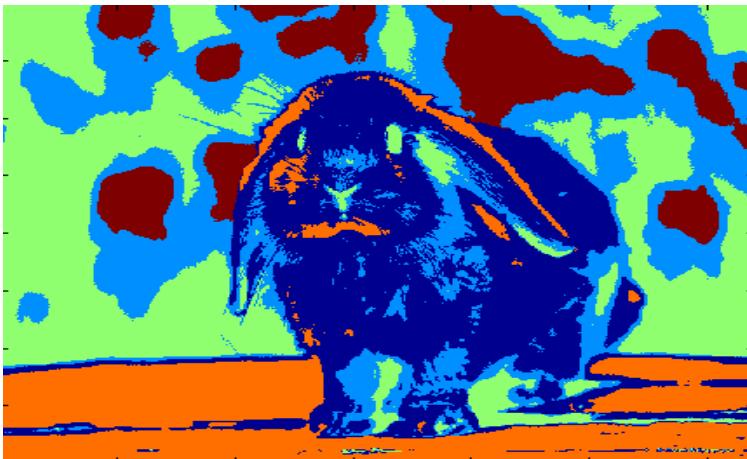

K-means menghasilkan
Pengelompokan yang kompak

Pada kasus ini, K-means ($K=2$) secara otomatis menemukan nilai ambang yang bagus (antara 2 cluster)

$k = 3$

(random colors are used to better show segments/clusters)

Contoh hasil *K-means clustering* (*berdasarkan warna*)

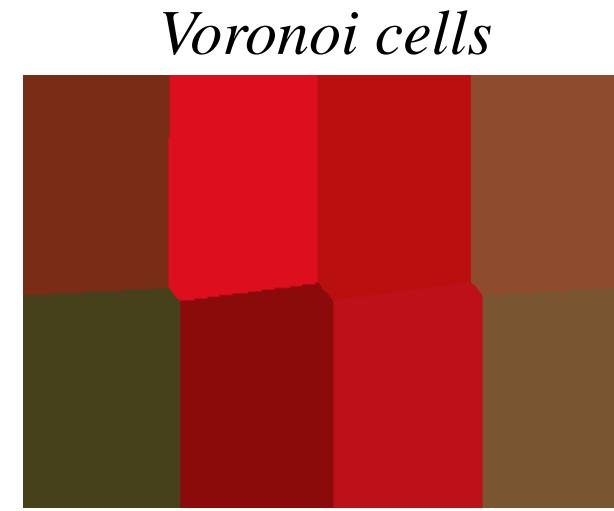

Contoh hasil *K-means clustering* (*berdasarkan warna + koordinat*)

RGB features

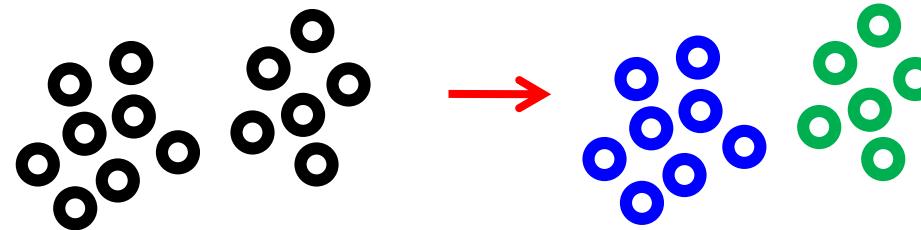

RGBXY features

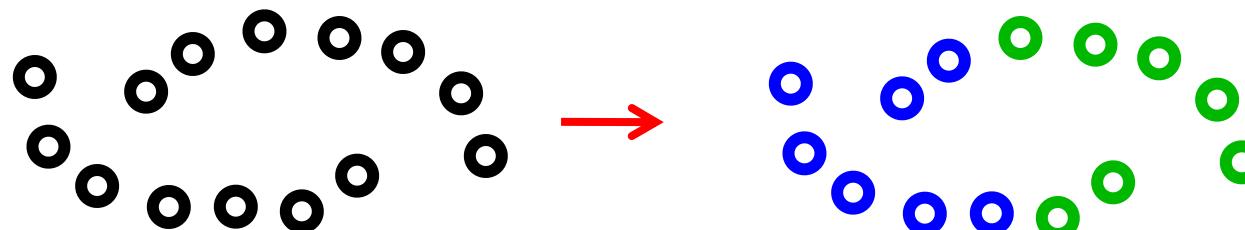

XY features only

Sifat-sifat K-means

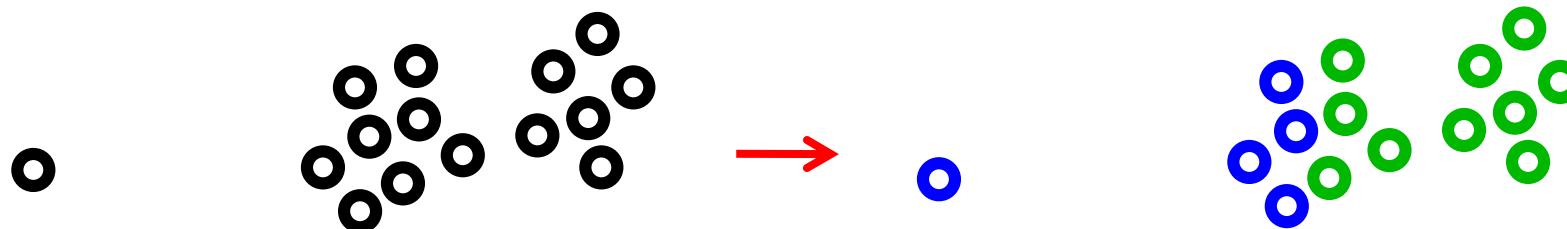

- Works best when clusters are spherical (blob like)

- Fails for elongated clusters
 - SSE is not an appropriate objective function in this case

- Sensitive to outliers

maximum likelihood (ML) fitting
of parameters μ_i (means) of Gaussian distributions

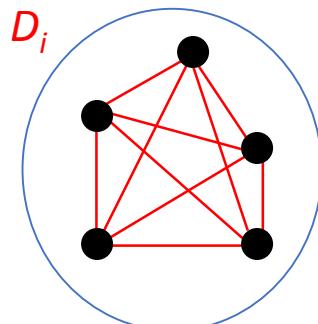

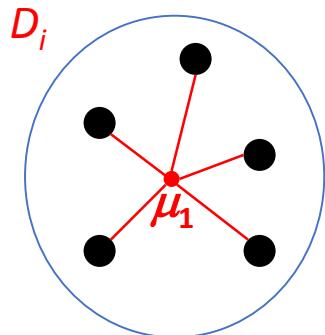

$$E_k = \sum_{i=1}^k \sum_{x \in D_i} \|x - \mu_i\|^2$$

equivalent (easy to check)

$$E_k \sim - \sum_{i=1}^k \sum_{x \in D_i} \log P(x | \mu_i) + const$$

Gaussian distribution $P(x | \mu_i) = \frac{1}{\sqrt{2\pi}\sigma} \exp\left(-\frac{\|x - \mu_i\|^2}{2\sigma^2}\right)$

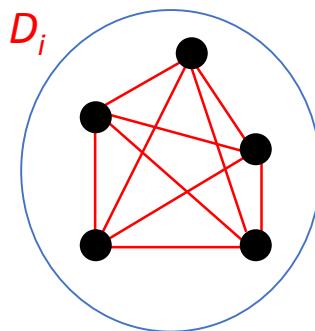

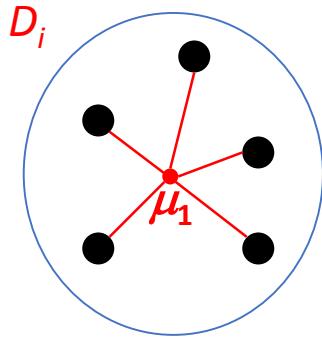

$$E_k = \sum_{i=1}^k \sum_{x \in D_i} \|x - \mu_i\|^2$$

equivalent (easy to check)

$$E_k = \sum_{i=1}^k \sum_{x, y \in D_i} \frac{\|x - y\|^2}{2 \cdot |D_i|}$$

sample variance: $\text{var}(D_i) = \frac{1}{|D_i|} \sum_{x \in D_i} \|x - \mu_i\|^2 = \frac{1}{2|D_i|^2} \sum_{x, y \in D_i} \|x - y\|^2$

just plug-in expression
 $\mu_i = \frac{1}{|D_i|} \sum_{y \in D_i} y$

both formulas can be written as

$$E_k = \sum_{i=1}^k |D_i| \cdot \text{var}(D_i)$$

sample variance: $\text{var}(D_i) = \frac{1}{|D_i|} \sum_{x \in D_i} \|x - \mu_i\|^2 = \frac{1}{2|D_i|^2} \sum_{x, y \in D_i} \|x - y\|^2$

Rangkuman K-means

- Advantages
 - Principled (objective function) approach to clustering
 - Simple to implement (the approximate iterative optimization)
 - Fast
 - Disadvantages
 - Only a local minimum is found (sensitive to initialization)
 - May fail for non-blob like clusters
 - Sensitive to outliers
 - Sensitive to choice of k
- K-means fits Gaussian models
- Quadratic errors are such
- Can add sparsity term and make k an additional variable

$$E = \sum_{i=1}^k \sum_{x \in D_i} \|x - \mu_i\|^2 + \gamma \cdot |k|$$

*Akaike Information Criterion (AIC) or
Bayesian Information Criterion (BIC)*
